# 1 Prelim : The Exponential Function and Hyperbolic Functions

## 1.1 Exponential Function

**Derivative**

$$\frac{d}{dt}\left(e^{at}\right) = a\, e^{at}$$

**Integral**

$$\int e^{at}\, dt = \frac{1}{a}e^{at} + C$$

## 1.2 Hyperbolic Functions

**Definitions:**

$$\sinh(at) = \frac{e^{at}-e^{-at}}{2} \ \Big| \ \cosh(at) = \frac{e^{at}+e^{-at}}{2} \ \Big| \ \tanh(at) = \frac{\sinh(at)}{\cosh(at)}.$$

**Derivatives**

$$\frac{d}{dt}\left(\sinh(at)\right) = a\,\cosh(at),\ \Big|\ \frac{d}{dt}\left(\cosh(at)\right) = a\,\sinh(at),\ \Big|\ \frac{d}{dt}\left(\tanh(at)\right) = a\,\text{sech}^2(at).$$

**Integrals**

$$\int \sinh(at)\, dt = \frac{1}{a}\cosh(at) + C$$

$$\int \cosh(at)\, dt = \frac{1}{a}\sinh(at) + C,$$

$$\int \tanh(at)\, dt = \frac{1}{a}\ln\left|\cosh(at)\right| + C.$$

**Common Identities**

$$\cosh^2 x - \sinh^2 x = 1,$$
$$\sinh(2x) = 2\,\sinh x\,\cosh x,$$
$$\cosh(2x) = \cosh^2 x + \sinh^2 x,$$
$$\tanh(2x) = \frac{2\,\tanh x}{1 + \tanh^2 x}.$$

## 1.3 Partial Fraction Decomposition

**Unrepeated Linear Factors**: A linear factor is of form $(ax + b)$

$$\frac{s+1}{s(s-2)(s+3)} = \frac{A}{s} + \frac{B}{s-2} + \frac{C}{s+3}$$

**Repeated LinearFactors**:

$$\frac{3}{(s+2)^2(s-3)} = \frac{A}{s+2} + \frac{B}{(s+2)^2} + \frac{C}{s-3}$$

**Unrepeated Quadratic Factors with complex roots**: Where the discriminant $(b^2 - 4ac)$ is negative (complex roots) but the factor is not repeated

$$\frac{3}{(s^2 - s + 1)(s+2)} = \frac{As + B}{s^2 - s + 1} + \frac{C}{s+2}$$

**Repeated Quadratic Factors with complex roots**:

$$\frac{1}{(s^2 + 1)^2(s-1)} = \frac{As + B}{(s^2 + 1)^2} + \frac{Cs + D}{s^2 + 1} + \frac{E}{s-1}$$

# 2  Laplace Transforms

## 2.1  What is a Laplace Transform?

The Laplace Transform, defined for $t \geq 0$, is given by

$$L\{f(t)\}(s) = F(s) = \int_0^\infty e^{-st} dt$$

## 2.2  Common Laplace Transforms

---

**Example Find the Laplace Transform of $f(t) = 1$**

We have:

$$L\{1\} = \int_0^\infty 1 \cdot e^{-st} dt = \lim_{R \to \infty} \int_0^R e^{-st} dt$$

This integral is equal to:

$$\int_0^R e^{-st} dt = \left. \frac{e^{-st}}{-s} \right|_{t=0}^{t=R} = -\frac{1}{s}[e^{-sR} - 1] = \frac{1 - e^{-sR}}{s}$$

Taking the limit as $R \to \infty$ gives:

$$L\{1\} = \lim_{R \to \infty} \frac{1 - e^{-sR}}{s} = \frac{1}{s}$$

---

**Example  Find the Laplace Transform of $f(t) = e^{2t}$**

$$L\{e^{2t}\} = \int_0^\infty e^{2t} e^{-st}\, dt = \int_0^\infty e^{-(s-2)t}\, dt$$

$$= \lim_{R \to \infty} \int_0^R e^{-(s-2)t}\, dt$$

$$= \lim_{R \to \infty} \left[ \frac{e^{-(s-2)t}}{-(s-2)} \right]_{t=0}^{t=R}$$

$$= \lim_{R \to \infty} \left( \frac{e^{-(s-2)R} - e^0}{-(s-2)} \right) = \lim_{R \to \infty} \left( \frac{e^{-(s-2)R} - 1}{-(s-2)} \right)$$

$$= \frac{1}{s-2} \quad \text{(since } e^{-(s-2)R} \to 0 \text{ as } R \to \infty \text{ provided } s > 2\text{)}$$

---

**Example Find the Laplace Transform of $f(t) = \cosh(at)$**

We have:

$$L\{\cosh(at)\} = L\left\{ \frac{e^{at} + e^{-at}}{2} \right\} \quad \text{from the definition of } \cosh(at)$$

$$= \frac{1}{2}L\{e^{at}\} + \frac{1}{2}L\{e^{-at}\} \quad \text{by linearity of the Laplace Transform}$$

$$= \frac{1}{2}\left( \frac{1}{s-a} \right) + \frac{1}{2}\left( \frac{1}{s+a} \right)$$

Hence:

$$L\{\cosh(at)\} = \frac{s}{s^2 - a^2}$$

Noting that $\sinh(at) = (e^{at} - e^{-at})/2$, we can find that:

$$L\{\sinh(at)\} = \frac{a}{(s^2 - a^2)}$$

---

**Example Find the Laplace Transform of $\cos(wt)$ and $\sin(wt)$ where $w$ is a constant.**

We first compute the Laplace Transform of $e^{iwt}$ using its definition:

$$L\{e^{iwt}\} = \int_0^\infty e^{-st} e^{iwt}\, dt = \int_0^\infty e^{-(s-iw)t}\, dt = \frac{1}{s - iw}, \quad \text{for } \Re(s) > 0.$$

To express this in terms of real and imaginary parts, we multiply the numerator and denominator by the complex conjugate of the denominator:

$$\frac{1}{s - iw} = \frac{s + iw}{(s - iw)(s + iw)} = \frac{s + iw}{s^2 + w^2}.$$

Since Euler's formula gives:

$$e^{iwt} = \cos(wt) + i\sin(wt),$$

the linearity of the Laplace Transform yields:

$$L\{e^{iwt}\} = L\{\cos(wt)\} + iL\{\sin(wt)\}.$$

Equating the two representations of $L\{e^{iwt}\}$, we have:

$$L\{\cos(wt)\} + iL\{\sin(wt)\} = \frac{s + iw}{s^2 + w^2}.$$

Since the equality must hold for both the real and imaginary parts, we equate them separately:

$$L\{\cos(wt)\} = \frac{s}{s^2 + w^2} \quad \text{and} \quad L\{\sin(wt)\} = \frac{w}{s^2 + w^2}.$$

## 2.3   Linearity of the Laplace Transform

The Laplace Transform is a linear operator, i.e. for any constants $a$ and $b$:

$$L\{af(t) + bg(t)\} = aL\{f(t)\} + bL\{g(t)\}$$

**Proof**

$$\begin{aligned}
L\{af(t) + bg(t)\} &= \int_0^\infty e^{-st}(af(t) + bg(t))\, dt \\
&= a\int_0^\infty e^{-st} f(t)\, dt + b\int_0^\infty e^{-st} g(t)\, dt \\
&= aL\{f(t)\} + bL\{g(t)\}
\end{aligned}$$

## 2.4 The First Shift Theorem

**Theorem First Shift Theorem**

If $f(t)$ has a Laplace Transform, $F(s)$, defined for $s > k$, then $e^{at} f(t)$ has a Laplace Transform, $F(s-a)$ defined for $s - a > k$ and is given by:

$$L\{e^{at} f(t)\} = F(s-a)$$

or, taking the inverse Laplace Transform of both sides:

$$e^{at} f(t) = L^{-1}\{F(s-a)\}$$

**Example Find the Laplace Transform of $e^{at} \cos(wt)$, where $a, w$ are constants.**

We know that $L\{\cos(wt)\} = \frac{s}{s^2+w^2}$, so by the First Shift Theorem:

$$L\{e^{at} \cos(wt)\} = \frac{s-a}{(s-a)^2 + w^2}$$
$$= \frac{s-a}{s^2 - 2as + a^2 + w^2}$$

## 2.5 Existence of the Laplace Transform

Existence of a Laplace transform is not always guaranteed because we're integrating over an infinite integral. For a Laplace Transform to exist for a given $s$, then the integral must exist:

$$\int_0^\infty e^{-st} f(t)\, dt$$

**Theorem Existence Theorem of Laplace Transforms**

Suppose $f(t)$ is a piecewise continuous function on $[0, \infty)$. If $f(t)$ satisfies:

$$|f(t)| \le Me^{kt} \ (0 \le t \le \infty)$$

for some constants, $M, k$, then the Laplace Transform of $f(t)$ exists for $s > k$. In other words, the Laplace Transform of $f(t)$ exists if $f(t)$ is bounded by an exponential function.

**Proof**

If $s > k$, then from the equation above, we have:

$$|F(s)| = \left| \int_0^\infty f(t) e^{-st}\, dt \right| \le \int_0^\infty |f(t)| e^{-st}\, dt \le \int_0^\infty Me^{(k-s)t}\, dt = \frac{M}{s-k}$$

## 2.6  Integration by Parts

Starting with the product rule:

$$\frac{d}{dx}[uv] = u'v + uv',$$

we can express this in differential form as:

$$d(uv) = u\,dv + v\,du.$$

Integrate both sides with respect to $x$:

$$\int d(uv) = \int_a^b u\,dv + \int_a^b v\,du.$$

The Fundamental Theorem of Calculus tells us that the left-hand side is simply:

$$uv = \int_a^b u\,dv + \int_a^b v\,du.$$

Rearrange to solve for the desired integral:

$$\int_a^b u\,dv = uv - \int_a^b v\,du,$$

---

**Example Use integration by parts to find the Laplace of $f(t) = t$**

$$L\{t\} = \int_0^\infty te^{-st}\,dt$$

We integrate by parts by setting:

$$u = t, \quad dv = e^{-st}, \quad du = 1, \quad v = -\frac{e^{-st}}{s}$$

Then intengrating by parts gives:

$$L\{t\} = \left[-\frac{te^{-st}}{s}\right]_0^\infty + \frac{1}{s}\int_0^\infty e^{-st}\,dt$$

$$= 0 + \frac{1}{s}\left[-\frac{e^{-st}}{s}\right]_0^\infty$$

Hence:

$$L\{t\} = \frac{1}{s^2}$$

---

**Example Use integration by parts to find the Laplace of $f(t) = \cos(t)$**

Let:

$$u = e^{-st}, \quad du = -se^{-st}, \quad dv = \cos(t), \quad v = \sin(t)$$

Then:

$$\int_0^\infty e^{-st}\cos(t)\,dt = \left[e^{-st}\sin(t)\right]_0^\infty + \int_0^\infty \sin(t)\cdot se^{-st}\,dt = 0 + s\int_0^\infty e^{-st}\sin(t)dt$$

Considering the sin part :

$$u = e^{-st}, \quad du = -se^{-st}, \quad dv = \sin(t), \quad v = -\cos(t)$$

$$\int_0^\infty e^{-st}\sin(t)\,dt = 1 - s\int_0^\infty e^{-st}\cos(t)\,dt$$

Substituting this back into the original integral gives:

$$\int_0^\infty e^{-st}\cos(t)\,dt = 1 - s\int_0^\infty e^{-st}\cos(t)\,dt = s - s^2\int_0^\infty e^{-st}\cos(t)\,dt$$

$$L\{cos(t)\} = \frac{s}{1+s^2}$$

## 2.7   Table of Laplace Transforms

| $f(t)$ | $L\{f(t)\}$ |
|---|---|
| $1$ | $\frac{1}{s}$, $s > 0$ |
| $t$ | $\frac{1}{s^2}$, $s > 0$ |
| $t^n$, $n = 0, 1, 2, 3$ | $\frac{n!}{s^{n+1}}$, $s > 0$ |
| $e^{at}$ | $\frac{1}{s-a}$, $s > a$ |
| $\cos(\omega t)$ | $\frac{s}{s^2+\omega^2}$ |
| $\sin(\omega t)$ | $\frac{\omega}{s^2+\omega^2}$ |
| $\cosh(at)$ | $\frac{s}{s^2-a^2}$, $s > a \geq 0$ |
| $\sinh(at)$ | $\frac{a}{s^2-a^2}$, $s > a \geq 0$ |
| $e^{at}\cos(\omega t)$ | $\frac{s-a}{(s-a)^2+\omega^2}$ |
| $e^{at}\sin(\omega t)$ | $\frac{\omega}{(s-a)^2+\omega^2}$ |
| $e^{at}f(t)$ | $F(s-a)$ |

## 2.8   Laplace Transforms of Derivatives

**Theorem Laplace Transform of Derivatives**

Suppose that $f(t)$ and $f'(t)$ are continous and that $|f(t)| \leq Me^{kt}, \forall t \geq 0$ and for constans $M, k$. Then the Laplace Transform of $f'(t)$ exists for $s > k$ and is given by:

$$L\left\{\frac{df}{dt}\right\} = sL\{f\} - f(0) \quad \text{for } s > k$$

We can easily extend this to higher order derivatives. Assume the Laplace Transform of $f^{(n)}(t)$ exists for $s > k$ and is given by:

$$L\left\{\frac{df^n}{dt^n}\right\} = s^n L\{f\} - s^{n-1}f(0) - s^{n-2}f'(0) - \ldots - f^{(n-1)}(0) \quad \text{for } s > k$$

**Example Find $L\{t^2\}$ using the fact $L\{s\} = 1/s$ for $s > 0$**

$$L\{f''\} = s^2 L\{f\} - sf(0) - f'(0)$$

With $f(t) = t^2$. Since $f'(t) = 2t$, $f''(t) = 2$, $f'(0) = 0$, $f(0) = 0$, gives:

$$L\{2\} = s^2 L\{t^2\} - s \cdot 0 - 0$$

So that:

$$L\{t^2\} = \frac{L\{2\}}{s^2} = \frac{2}{s^3}$$

**Example Find $L\{\sin(t)\}$ and $L\{\cos(t)\}$**

We again use ther equation:
$$L\{f''\} = s^2 L\{f\} - sf(0) - f'(0)$$

With $f(t) = \sin(t)$, $f'(t) = \cos(t)$, $f''(t) = -\sin(t)$, $\sin(0) = 0$, $\cos(0) = 1$. This gives:

$$L\{-\sin(t)\} = s^2 L\{\sin(t)\} - s \cdot 0 - 1$$

So that:

$$L\{\sin(t)\} = \frac{1}{s^2 + 1}$$

Similarly, we can find:

$$L\{\cos(t)\} = \frac{s}{s^2 + 1}$$

## 2.9    Solving Initial Value Problems

Consider an example from mechanics: A particle of mass $m > 0$ lies on rough table, attatched to a spring of stiffness $k > 0$. At any time $t > 0$, the mass is a distance $x(t)$ from the equillibrium position $O$, and $x(t)$ is much less than the length of the spring.

The mass is subject to a driving force $F_d(t)$, from Newtons second law, we have:

$$F_d(t) - kx - \gamma \frac{dx}{dt} = m \frac{dx^2}{dt^2}$$

Where $\gamma > 0$ is the **damping constant** and the term $\gamma \frac{dx}{dt}$ models the **fricition due to roughness** of the table, which oppposes direction of motion. The **restoring force** due to the spring is $-kx$; and always points towards $O$. The term $m\frac{dx^2}{dt^2}$ is the **acceleration of the mass**. We can rewrite this as:

$$F_d(t) = m \frac{dx^2}{dt^2} + \gamma \frac{dx}{dt} + kx$$

In order to solve this, we also need initial displacement $v_0 = x(0)$ and initial velocity $v_0 = \frac{dx}{dt}(0)$.

---

**Example**

$$\frac{dx^2}{dt^2} + 3\frac{dx}{dt} + 2x = 0, \quad x(0) = 0, \quad \frac{dx}{dt}(0) = 1$$

1. **Take Laplace of governing equation:**

$$L\left\{\frac{dx^2}{dt^2}\right\} = s^2 L\{x\} - sx(0) - x'(0) = s^2 L\{x\} - 1$$

$$L\left\{\frac{dx}{dt}\right\} = sL\{x\} - x(0) = sLx$$

Hence:

$$s^2 L\{x\} - 1 + 3sL\{x\} + 2L\{x\} = 0$$

This is known as the **subsidary equation**. Rearranging:

$$(s^2 + 3s + 2)L\{x\} = 1$$

2. **Solve the subsidary equation:**

$$L\{x\} = \frac{1}{s^2 + 3s + 2}$$

3. **Find the inverse Laplace Transform:**

$$x(t) = L^{-1}\left\{\frac{1}{s^2 + 3s + 2}\right\} = L^{-1}\left\{\frac{1}{(s+1)(s+2)}\right\}$$

$$\frac{1}{(s+1)(s+2)} = \frac{A}{s+1} + \frac{B}{s+2} = \frac{A(s+2) + B(s+1)}{(s+1)(s+2)}$$

Hence:

$$A(s+2) + B(s+1) = 1 \quad \rightarrow A = 1, B = -1$$

Thus:

$$x = L^{-1}\left\{\frac{1}{s+1} - \frac{1}{s+2}\right\} = L^{-1}\left\{\frac{1}{s+1}\right\} - L^{-1}\left\{\frac{1}{s+2}\right\} = e^{-t} - e^{-2t}$$

## 2.10 Heaviside Step Function

Denote the Heaviside Step Function as $H(t)$, defined as:

$$H(t) = \begin{cases} 0 & \text{if } t < 0 \\ 1 & \text{if } t > 0 \end{cases}$$

Clearly, for any constant $a$, we have:

$$H(t - a) = \begin{cases} 0 & \text{if } t < a \\ 1 & \text{if } t > a \end{cases}$$

---

**Example Express this function in terms of a Heaviside step function**

$$f(t) = \begin{cases} 3 & \text{for } 0 \leq t < 2 \\ -1 & \text{for } t > 2 \end{cases}$$

We write the general form of $f(t)$ as:
$$f(t) = \alpha + \beta H(t - 2)$$

Now, settings $t$ to any value $\in [0, 2)$ gives:

$$f(t) = \alpha + (\beta)(0) = 0 \Rightarrow \alpha = 3$$

Setting $t$ to any value greater than 2 gives:

$$f(t) = 3 + (\beta)(1) = -1 \Rightarrow \beta = -4$$

Thus, we have:

$$f(t) = 3 - 4H(t - 2)$$

---

**Example Express this function in terms of a Heaviside step function**

$$f(t) = \begin{cases} 3 & \text{for } 0 \leq t < 1 \\ 5 & \text{for } 1 < t < 3 \\ -2 & \text{for } t > 3 \end{cases}$$

We write the general form of $f(t)$ as:

$$f(t) = \alpha + \beta H(t - 1) + \gamma H(t - 3)$$

Setting $t$ to any value $\in [0, 1)$ gives: $f(t) = \alpha + (\beta)(0) + (\gamma)(0) = 0 \Rightarrow \alpha = 3$
Setting $t$ to any value $\in (1, 3)$ gives: $f(t) = 3 + (\beta)(2) + (\gamma)(0) = 5 \Rightarrow \beta = 2$
Setting $t$ to any value greater than 3 gives: $f(t) = 3 + 2 + (\gamma)(1) = -7 \Rightarrow \gamma = -5$ Thus, we have:

$$f(t) = 3 + 2H(t - 1) - 7H(t - 3)$$

## 2.11 The Second Shift Theorem

**Theorem**

If $f(t)$ has the transform $F(s)$ $(s > k)$ then the shifted function,

$$\tilde{f}(t) = f(t-a)H(t-a) = \begin{cases} 0 & \text{if } t < a \\ f(t-a) & \text{if } t > a \end{cases}$$

has the transform $e^{-as}F(s)$ $(s > k)$, that is:

$$L\{f(t-a)H(t-a)\} = e^{-as}F(s)$$

**Proof**

$$L\{f(t-a)H(t-a)\} = \int_0^\infty e^{-st}f(t-a)H(t-a)\,dt = \int_a^\infty e^{-st}f(t-a)\,dt$$

We introduce a new integration variable $\tau = t - a$, we have

$$\int_0^\infty e^{-s(\tau+a)}f(\tau)\,d\tau = e^{-as}\int_0^\infty e^{-s\tau}f(\tau)\,d\tau = e^{-as}F(s)$$

**Example : Find the Laplace Transform of $H(t-a)$ for $a > 0$**

$$L\{H(t-a)\} = L\{H(t-a)f(t-a)\} = e^{-as}F(s) = \frac{e^{-as}}{s}$$

## 2.12 Heaviside Step Function

Denote the Heaviside Step Function as $H(t)$, defined as:

$$H(t) = \begin{cases} 0 & \text{if } t < 0 \\ 1 & \text{if } t > 0 \end{cases}$$

Clearly, for any constant $a$, we have:

$$H(t-a) = \begin{cases} 0 & \text{if } t < a \\ 1 & \text{if } t > a \end{cases}$$

**Example Express this function in terms of a Heaviside step function**

$$f(t) = \begin{cases} 3 & \text{for } 0 \le t < 2 \\ -1 & \text{for } t > 2 \end{cases}$$

We write the general form of $f(t)$ as:

$$f(t) = \alpha + \beta H(t-2)$$

Now, settings $t$ to any value $\in [0, 2)$ gives:

$$f(t) = \alpha + (\beta)(0) = 0 \Rightarrow \alpha = 3$$

Setting $t$ to any value greater than 2 gives:

$$f(t) = 3 + (\beta)(1) = -1 \Rightarrow \beta = -4$$

Thus, we have:

$$f(t) = 3 - 4H(t-2)$$

**Example Express this function in terms of a Heaviside step function**

$$f(t) = \begin{cases} 3 & \text{for } 0 \leq t < 1 \\ 5 & \text{for } 1 < t < 3 \\ -2 & \text{for } t > 3 \end{cases}$$

We write the general form of $f(t)$ as:

$$f(t) = \alpha + \beta H(t - 1) + \gamma H(t - 3)$$

Setting $t$ to any value $\in [0, 1)$ gives: $f(t) = \alpha + (\beta)(0) + (\gamma)(0) = 0 \Rightarrow \alpha = 3$
Setting $t$ to any value $\in (1, 3)$ gives: $f(t) = 3 + (\beta)(2) + (\gamma)(0) = 5 \Rightarrow \beta = 2$
Setting $t$ to any value greater than 3 gives: $f(t) = 3 + 2 + (\gamma)(1) = -7 \Rightarrow \gamma = -5$ Thus, we have:

$$f(t) = 3 + 2H(t - 1) - 7H(t - 3)$$

## 2.13 The Second Shift Theorem

**Theorem**

If $f(t)$ has the transform $F(s)$ $(s > k)$ then the shifted function,

$$\tilde{f}(t) = f(t-a)H(t-a) = \begin{cases} 0 & \text{if } t < a \\ f(t-a) & \text{if } t > a \end{cases}$$

has the transform $e^{-as}F(s)$ $(s > k)$, that is:

$$L\{f(t-a)H(t-a)\} = e^{-as}F(s)$$

**Proof**

$$L\{f(t-a)H(t-a)\} = \int_0^\infty e^{-st} f(t-a)H(t-a) \, dt = \int_a^\infty e^{-st} f(t-a) \, dt$$

We introduce a new integration variable $\tau = t - a$, we have

$$\int_0^\infty e^{-s(\tau+a)} f(\tau) \, d\tau = e^{-as} \int_0^\infty e^{-s\tau} f(\tau) \, d\tau = e^{-as}F(s)$$

**Example : Find the Laplace Transform of $H(t-a)$ for $a > 0$**

$$L\{H(t-a)\} = L\{H(t-a)f(t-a)\} = e^{-as}F(s) = \frac{e^{-as}}{s}$$

## 2.14 Practice Problems

1. Use the First Shift Theorem $(L\{e^{at}f(t)\} = F(s-a))$ to find the Laplace transform of the following functions:

   (a) $t^3 e^{-3t}$ (b) $e^{-t}\cos(2t)$ (c) $e^{-4t}\cosh(5t)$ (d) $e^{-t}\sin^2(t)$

2. Use the First Shift Theorem $(L^{-1}\{F(s-a)\} = e^{at}f(t))$ to find the inverse Laplace transform of the following functions:

   (a) $\dfrac{6s-4}{s^2-4s+20}$ (b) $\dfrac{3s+7}{s^2-2s-3}$ (c) $\dfrac{4s+12}{s^2+8s+16}$

3. Solve the following initial value problems using the method of Laplace transforms:

$$y'' + y' - 6y = 0, \quad y(0) = 0, \quad y'(0) = 1;$$
$$y'' - y = t, \quad y(0) = 1, \quad y'(0) = 1.$$

4. Find the inverse Laplace transform of the following functions using the method of partial fractions:

   (a) $\dfrac{2s^2-4}{(s+1)(s-2)(s-3)}$. (b) $\dfrac{5s^2-15s-11}{(s+1)(s-2)^3}$. (c) $\dfrac{3s+1}{(s-1)(s^2+1)}$. (d) $\dfrac{e^{-5s}}{(s^2+1)(s^2+2)}$.

## 2.15 Heaviside Step Function

Denote the Heaviside Step Function as $H(t)$, defined as:

$$H(t) = \begin{cases} 0 & \text{if } t < 0 \\ 1 & \text{if } t > 0 \end{cases}$$

Clearly, for any constant $a$, we have:

$$H(t-a) = \begin{cases} 0 & \text{if } t < a \\ 1 & \text{if } t > a \end{cases}$$

**Example Express this function in terms of a Heaviside step function**

$$f(t) = \begin{cases} 3 & \text{for } 0 \le t < 2 \\ -1 & \text{for } t > 2 \end{cases}$$

We write the general form of $f(t)$ as:

$$f(t) = \alpha + \beta H(t-2)$$

Now, settings $t$ to any value $\in [0,2)$ gives:

$$f(t) = \alpha + (\beta)(0) = 0 \Rightarrow \alpha = 3$$

Setting $t$ to any value greater than 2 gives:

$$f(t) = 3 + (\beta)(1) = -1 \Rightarrow \beta = -4$$

Thus, we have:

$$f(t) = 3 - 4H(t-2)$$

**Example Express this function in terms of a Heaviside step function**

$$f(t) = \begin{cases} 3 & \text{for } 0 \le t < 1 \\ 5 & \text{for } 1 < t < 3 \\ -2 & \text{for } t > 3 \end{cases}$$

We write the general form of $f(t)$ as:

$$f(t) = \alpha + \beta H(t-1) + \gamma H(t-3)$$

Setting $t$ to any value $\in [0,1)$ gives: $f(t) = \alpha + (\beta)(0) + (\gamma)(0) = 0 \Rightarrow \alpha = 3$
Setting $t$ to any value $\in (1,3)$ gives: $f(t) = 3 + (\beta)(2) + (\gamma)(0) = 5 \Rightarrow \beta = 2$
Setting $t$ to any value greater than 3 gives: $f(t) = 3 + 2 + (\gamma)(1) = -7 \Rightarrow \gamma = -5$ Thus, we have:

$$f(t) = 3 + 2H(t-1) - 7H(t-3)$$

## 2.16　The Second Shift Theorem

**Theorem**

If $f(t)$ has the transform $F(s)$ $(s > k)$ then the shifted function,

$$\tilde{f}(t) = f(t-a)H(t-a) = \begin{cases} 0 & \text{if } t < a \\ f(t-a) & \text{if } t > a \end{cases}$$

has the transform $e^{-as}F(s)$ $(s > k)$, that is:

$$L\{f(t-a)H(t-a)\} = e^{-as}F(s)$$

**Proof**

$$L\{f(t-a)H(t-a)\} = \int_0^\infty e^{-st} f(t-a)H(t-a)\, dt = \int_a^\infty e^{-st} f(t-a)\, dt$$

We introduce a new integration variable $\tau = t - a$, we have

$$\int_0^\infty e^{-s(\tau+a)} f(\tau)\, d\tau = e^{-as}\int_0^\infty e^{-s\tau} f(\tau)\, d\tau = e^{-as}F(s)$$

**Example : Find the Laplace Transform of $H(t-a)$ for $a > 0$**

$$L\{H(t-a)\} = L\{H(t-a)f(t-a)\} = e^{-as}F(s) = \frac{e^{-as}}{s}$$

## 2.17　The Dirac Delta Function

The **Dirac Delta Function** models extremely brief but intense forces like a hammer hitting a nail. It starts as a function $\delta_\varepsilon$, that equals $\frac{1}{2\varepsilon}$ over the interval $t \in [-\varepsilon, \varepsilon]$ and 0 elsewhere.

$$\delta_\epsilon(t) = \begin{cases} \dfrac{1}{2\epsilon} & \text{if } t \in [-\epsilon, \epsilon], \\ 0 & \text{otherwise.} \end{cases}$$

This function creates a rectangular pulse with the following propertites:

$$\textbf{Height: } \frac{1}{2\varepsilon} \quad \textbf{Width: } 2\varepsilon \quad \textbf{Area: } 1 \text{ (always)}$$

As $\varepsilon$ approaches 0, the function becomes infinitely tall and thin, but the area remains 1. This limit defines the Dirac Delta Function:

$$\delta(t) = \lim_{\varepsilon \to 0+} \{\delta_\varepsilon(t)\}$$

**Properties of the Dirac Delta Function:**

$$\delta(t) = 0 \text{ for } t \neq 0$$
$$\int_{-\infty}^\infty \delta(t)\, dt = 1$$
$$\int_{-\infty}^\infty \delta(t-t_0)f(t)\, dt = f(t_0)$$

The Laplace Transform of the Dirac Delta Function is:

$$L\{\delta(t-t_0)\} = \int_0^\infty e^{-st}\delta(t-t_0)\, dt = \int_{-\infty}^\infty e^{-st}\delta(t-t_0)\, dt = e^{-st_0} \quad \text{for } t_0 > 0$$

14

**Example : Solve the following initial value problem which governs the behavious of an RLC circuit**

$$LQ'' + RQ' + \frac{Q}{C} = V_0\delta(t - a)$$
$$Q(0) = 0$$
$$Q'(0) = 0$$

Where $a, L, R, C, V_0$ are all positive constans and $4L > R^2C$.

Note that the applied voltage corresponds to an impulse of stength $V_0$ at $t = a$

We note that:

$$L\{Q''\} = s^2 L\{Q\} - sQ(0) - Q'(0) = s^2 L\{Q\}$$
$$L\{Q'\} = sL\{Q\} - Q(0) = sL\{Q\}$$
$$L\{\delta(t - a)\} = e^{-sa} = e^{-as}$$

Thus:

$$L\{LQ'' + RQ' + \frac{Q}{C} = V_0\delta(t - a)\} = Ls^2 L\{Q\} + RsL\{Q\} + \frac{1}{C}L\{Q\} = V_0 e^{-as}$$

Grouping terms:

$$L\{Q\}(Ls^2 + Rs + \frac{1}{C}) = V_0 e^{-as}$$

Hence:

$$L\{Q\} = V_0 e^{-as} \cdot \frac{1}{Ls^2 + Rs + \frac{1}{C}}$$

Removing the $L$ from the denominator gives:

$$L\{Q\} = \frac{V_0}{L} e^{-as} \cdot \frac{1}{s^2 + \frac{R}{L}s + \frac{1}{LC}}$$
$$= \frac{V_0}{L} \cdot \frac{e^{-as}}{s^2 + \frac{R}{L}s + \frac{1}{LC}}$$

We notice that:

$$(s + \frac{R}{2L})^2 = s^2 + s\frac{2R}{2L} + \frac{R^2}{4L^2}$$
$$= s^2 + \frac{R}{L}s + \frac{R^2}{4L^2}$$

We also note that:

$$L\{\sin(\beta t)\} = \frac{\beta}{s^2 + B^2} \xrightarrow{\text{First Shift Theorem}} L\{e^{-as}\sin(\beta t)\} = \frac{B}{(s + a)^2 + \beta^2}$$

Or,

$$L^{-1}\{\frac{B}{(s + a)^2 + \beta^2}\} = e^{-at}\sin(\beta t)$$

We can also write:

$$L^{-1}\{F(s)\} = f(t)$$
